Standard Procedure for 2-Person Adult CPR Training and Teaching Notes

2-Person CPR

Two-rescuer cardiopulmonary resuscitation (CPR) involves two trained individuals working as a team to provide continuous, high-quality chest compressions and ventilation, reducing rescuer fatigue and improving circulation to the patient. The Royal Life Saving Society (RLSS) recommends that in drowning cases (where hypoxia is the primary issue), two rescuers should deliver 5 initial rescue breaths before commencing 30 compressions and 2 breaths.

Safety Training

The standard procedure for 2-person adult CPR:

2-Rescuer CPR Procedure (Adult)

A) Roles:

- One rescuer (Compressor) focuses on chest compressions, while the second rescuer (Ventilator) manages the airway and breaths.
- Ratio: 30 compressions followed by 2 breaths.
- Compression Depth/Rate: Push hard (at least 4 to 6 cm) and fast (100–120 beats per minute).

B) Switching:

- Rescuers should switch roles every 5 cycles (about 2 minutes) to avoid fatigue and ensure high-quality CPR.

C) Switch Procedure:

- Compressor calls out "Switch" at the end of the 4th cycle compression
- (“1&2&3&4&25” becomes “1&2&3&4&Switch”), and
- Roles are swapped immediately.

For Singapore First Aid Training guidelines

Specific Situations

Child/Infant: For 2-person CPR on children or infants, the ratio changes to 15 compressions followed by 2 breaths.

Key Performance Tips

1. **Count Aloud:**
    a. The Compressor should count the 30 compressions aloud to coordinate with the Ventilator.
2. **Avoid Leaning:**
    a. Do not lean on the chest between compressions to allow for full chest recoil.
3. **Breaths**:
    a. Ensure the chest rises with each breath.
